

Linear algebra hw 0.5

① a) $2x + y - 2z = 10$

$3x + 2y - 2z = 1$

$5x + 4y + 3z = 4$

$$\begin{pmatrix} 2 & 1 & -2 & | & 10 \\ 3 & 2 & -2 & | & 1 \\ 5 & 4 & 3 & | & 4 \end{pmatrix}$$

$$|A| = \begin{vmatrix} 2 & 1 & -2 & | & 10 \\ 3 & 2 & -2 & | & 1 \\ 5 & 4 & 3 & | & 4 \end{vmatrix} = 2 \begin{vmatrix} 2 & -2 \\ 4 & 3 \end{vmatrix} - \begin{vmatrix} 3 & -2 \\ 5 & 3 \end{vmatrix} - 2 \begin{vmatrix} 3 & 2 \\ 5 & 4 \end{vmatrix} = 28 - 19 - 4 = 5 \neq 0$$

the determinant is not 0, therefore there is only 1 solution

$$x = \frac{|A_{1b}|}{|A|} = \frac{\begin{vmatrix} 10 & 1 & -2 \\ 1 & 2 & -2 \\ 4 & 4 & 3 \end{vmatrix}}{5} = \frac{1}{5} (10 \cdot 4 \cdot 4 - 11 \cdot 2 \cdot 4) = \frac{137}{5} = 27.4$$

$$y = \frac{|A_{2b}|}{|A|} = \frac{\begin{vmatrix} 2 & 4 & -2 \\ 3 & 1 & -2 \\ 5 & 10 & 3 \end{vmatrix}}{5} = \frac{1}{5} (2 \cdot 11 - 10 \cdot 19 - 2 \cdot 7) = -36.4 \Rightarrow \begin{pmatrix} x \\ y \\ z \end{pmatrix} \Rightarrow \begin{pmatrix} 27.4 \\ -36.4 \\ 4.2 \end{pmatrix}$$

$$z = \frac{|A_{3b}|}{|A|} = \frac{\begin{vmatrix} 2 & 1 & 10 \\ 3 & 2 & 1 \\ 5 & 4 & 4 \end{vmatrix}}{5} = \frac{1}{5} (2 \cdot 4 - 7 + 10 \cdot 2) = 4.2$$

② c) $A = \begin{bmatrix} 1 & 2 & 3 \\ 1 & 3 & 4 \\ 1 & 4 & 3 \end{bmatrix}$

$$C_{11} = (-1)^2 |A_{11}| = \begin{vmatrix} 3 & 4 \\ 4 & 3 \end{vmatrix} = -7 \quad C_{21} = (-1)^3 |A_{21}| = \begin{vmatrix} 2 & 3 \\ 4 & 3 \end{vmatrix} = 6 \quad C_{31} = (-1)^4 |A_{31}| = \begin{vmatrix} 2 & 3 \\ 3 & 4 \end{vmatrix} = -1$$

$$C_{12} = (-1)^3 |A_{12}| = \begin{vmatrix} 1 & 4 \\ 1 & 3 \end{vmatrix} = 1 \quad C_{22} = (-1)^4 |A_{22}| = \begin{vmatrix} 1 & 3 \\ 1 & 3 \end{vmatrix} = 0 \quad C_{32} = (-1)^5 |A_{32}| = \begin{vmatrix} 1 & 3 \\ 1 & 4 \end{vmatrix} = -1$$

$$C_{13} = (-1)^4 |A_{13}| = \begin{vmatrix} 1 & 3 \\ 1 & 4 \end{vmatrix} = 1 \quad C_{23} = (-1)^5 |A_{23}| = \begin{vmatrix} 1 & 2 \\ 1 & 4 \end{vmatrix} = -2 \quad C_{33} = (-1)^6 |A_{33}| = \begin{vmatrix} 1 & 2 \\ 1 & 3 \end{vmatrix} = 1$$

$\text{Adj}(A) = \text{cofactor}^T$

$$= \begin{bmatrix} -7 & 6 & 1 \\ 1 & 0 & -1 \\ 1 & -2 & 1 \end{bmatrix}$$

~~$$\begin{bmatrix} -7 & 6 & 1 \\ 1 & 0 & -1 \\ 1 & -2 & 1 \end{bmatrix}$$~~

$$\begin{vmatrix} 1 & 2 & 3 \\ 1 & 3 & 4 \\ 1 & 4 & 3 \end{vmatrix} = 1 \cdot (-7) - 2 \cdot (-1) + 3 \cdot 1 = -2$$

$$\Rightarrow \begin{bmatrix} -7 & 6 & 1 \\ 1 & 0 & -1 \\ 1 & -2 & 1 \end{bmatrix}$$

inverse matrix

$$\begin{bmatrix} -7 & 6 & 1 \\ 1 & 0 & -1 \\ 1 & -2 & 1 \end{bmatrix} \begin{bmatrix} -\frac{1}{2} & -3 & -\frac{1}{2} \\ \frac{1}{2} & 0 & -\frac{1}{2} \\ -\frac{1}{2} & 1 & -\frac{1}{2} \end{bmatrix}$$

③ Let A, B be square matrices of order n .

Prove : $\text{adj}(AB) = \text{adj}(B) \text{adj}(A)$

$$A \cdot \text{adj}(A) = \det(A) \cdot I$$

$$\therefore AB \cdot \text{adj}(AB) = \det(AB) \cdot I = \det(A) \cdot \det(B) \cdot I = \det(B) \cdot \det(A) \cdot I = \det(B) \cdot A \cdot \text{adj}(A)$$

$$\text{but } \det(B) \cdot A \cdot \text{adj}(A) = A \cdot \det(B) \cdot \text{adj}(A)$$

$$= A \cdot (\det(B) \cdot I) \cdot \text{adj}(A) = AB \cdot \text{adj}(B) \text{adj}(A)$$

$$\therefore AB \cdot \text{adj}(AB) = AB \cdot \text{adj}(B) \cdot \text{adj}(A)$$

Since A and B are of order n , they are invertible, and AB is invertible, therefore multiplying by $(AB)^{-1}$ on both sides gives

$$\text{adj}(AB) = \text{adj}(B) \cdot \text{adj}(A)$$

⑤ Given that $|A| = \pm 1$ and $A^{-1} = \text{adj}(A) / |A|$,

$$A^{-1} = \text{adj}(A) \text{ or } -\text{adj}(A)$$

$\text{adj}(A)$ is the matrix of cofactors transposed which must have only integer entries because all determinants must be integers (if a, b, c, d are integers, then $ac - bd$ is an integer). all integers multiplied by ± 1 are still integers, so A^{-1} must contain only integers
